

Study Definition and Scope Partitions

KJV 1611 / KJV 1769 Semantic Drift Study

Purpose

This document defines the study boundary, partition logic, and stable identity contract for the KJV 1611 / KJV 1769 semantic drift study. It establishes which text units are eligible for direct drift analysis, which units are preserved for future analysis, and how coverage exceptions are recorded.

Study Definition

The study quantifies semantic drift between aligned text units in the KJV 1611 and KJV 1769 editions. The primary comparison unit is the structural tuple composed of `work_code`, `division_level_1`, and `division_level_2`. These fields correspond to the book-level work identifier and its chapter and verse-level divisions.

Stable point identity is defined by combining the canon identifier with the structural text-unit tuple. The canonical stable identifier is formatted as `canon_id:work_code:division_level_1:division_level_2` and may be converted into a deterministic UUID through UUID version 5 when vector-store point identity requires UUID addressing.

Canon Partition Policy

The database feed is partitioned into three study-defined sets. These partitions preserve the distinction between aligned comparison material, KJV 1611 exclusive material, and coverage exceptions.

Partition	Definition	Analysis Role
Partition A: Shared Canon Drift Set	Units whose structural key exists in both KJV 1611 and KJV 1769.	Primary direct semantic drift analysis.
Partition B: KJV 1611 Only Set	Units present in KJV 1611 but absent from KJV 1769, including extra books.	Reserved for future nearest-neighbor and thematic mapping.
Partition C: Coverage and Exceptions	Records identifying matched units, unmatched units, and mismatch locations.	Coverage reporting and auditability.

Extraction Strategy

The extraction stage constructs structural key sets for both canons and assigns each text unit to the appropriate partition. Shared keys are derived from the intersection of the KJV 1611 and KJV 1769 key sets. KJV 1611 exclusive keys are derived from the set difference between the KJV 1611 key set and the KJV 1769 key set.

- $S_{1611} = \{(work_code, division_level_1, division_level_2)\}$
- $S_{1769} = \{(work_code, division_level_1, division_level_2)\}$
- Partition A = $S_{1611} \cap S_{1769}$
- Partition B = $S_{1611} - S_{1769}$

Study Contract

Component	Study Decision
Study	Semantic Drift Between KJV 1611 and KJV 1769

Study architecture artifact. Proprietary platform source code is not included in public release materials.

Primary objective	Quantify semantic drift for aligned text units between editions.
Alignment unit	(work_code, division_level_1, division_level_2)
Stable identity	canon_id:work_code:division_level_1:division_level_2
Primary partition	Shared canon intersection across KJV 1611 and KJV 1769
Exclusive partition	KJV 1611 units absent from KJV 1769, reserved for future analysis.

Expected Output Artifacts
